### **Data Science for Economists**

Lecture 5: Data cleaning & wrangling: (1) Tidyverse

Grant McDermott
University of Oregon | EC 607

## Table of contents

- 1. Prologue
- 2. Tidyverse basics
- 3. Data wrangling with dplyr
  - filter
  - arrange
  - select
  - mutate
  - summarise
  - joins
- 4. Data tidying with tidyr
  - pivot\_longer / pivot\_wider
  - separate
  - unite
- 5. Summary

# Prologue

# What is "tidy" data?

#### **Resources:**

- Vignette (from the **tidyr** package)
- Original paper (Hadley Wickham, 2014 JSS)

# What is "tidy" data?

#### **Resources:**

- Vignette (from the **tidyr** package)
- Original paper (Hadley Wickham, 2014 JSS)

### Key points:

- 1. Each variable forms a column.
- 2. Each observation forms a row.
- 3. Each type of observational unit forms a table.

# What is "tidy" data?

#### **Resources:**

- Vignette (from the **tidyr** package)
- Original paper (Hadley Wickham, 2014 JSS)

### Key points:

- 1. Each variable forms a column.
- 2. Each observation forms a row.
- 3. Each type of observational unit forms a table.

Basically, tidy data is more likely to be long (i.e. narrow) format than wide format.

## Checklist

R packages you'll need today

- **☑ tidyverse**
- **☑** nycflights13

## Checklist

### R packages you'll need today

- **☑** tidyverse
- **☑** nycflights13

I'll hold off loading these libraries for now. But you can install/update them both with the following command.

```
install.packages(c('tidyverse', 'nycflights13'), repos = 'https://cran.rstudio.com',
```

**Tip:** If you're on Linux, then I *strongly* recommend installing the pre-compiled binary versions of these packages from RSPM instead of CRAN. The exact repo mirror varies by distro (see the link). But on Ubuntu 20.04, for example, you'd use:

```
install.packages(c('tidyverse', 'nycflights13'), repos = 'https://packagemanager.rstuc
```

# Tidyverse basics

# Tidyverse vs. base R

Much digital ink has been spilled over the "tidyverse vs. base R" debate.

# Tidyverse vs. base R

Much digital ink has been spilled over the "tidyverse vs. base R" debate.

I won't delve into this debate here, because I think the answer is clear: We should teach the tidyverse first (or, at least, early).

- The documentation and community support are outstanding.
- Having a consistent philosophy and syntax makes it easier to learn.
- Provides a convenient "front-end" to big data tools that we'll use later in the course.
- For data cleaning, wrangling, and plotting, the tidyverse really is a no-brainer. 1

<sup>&</sup>lt;sup>1</sup> I'm also a huge fan of **data.table**. This package will be the subject of our next lecture.

# Tidyverse vs. base R

Much digital ink has been spilled over the "tidyverse vs. base R" debate.

I won't delve into this debate here, because I think the answer is clear: We should teach the tidyverse first (or, at least, early).

- The documentation and community support are outstanding.
- Having a consistent philosophy and syntax makes it easier to learn.
- Provides a convenient "front-end" to big data tools that we'll use later in the course.
- For data cleaning, wrangling, and plotting, the tidyverse really is a no-brainer. 1

**But**... this certainly shouldn't put you off learning base R alternatives.

- Base R is extremely flexible and powerful (and stable).
- There are some things that you'll have to venture outside of the tidyverse for.
- A combination of tidyverse and base R is often the best solution to a problem.
- Excellent base R data manipulation tutorials: here and here.

<sup>&</sup>lt;sup>1</sup> I'm also a huge fan of **data.table**. This package will be the subject of our next lecture.

# Tidyverse vs. base R (cont.)

One point of convenience is that there is often a direct correspondence between a tidyverse command and its base R equivalent.

These generally follow a tidyverse::snake\_case vs base::period.case rule. E.g. Compare:

tidyverse	base
?readr::read_csv	<pre>?utils::read.csv</pre>
?dplyr::if_else	?base::ifelse
<pre>?tibble::tibble</pre>	?base::data.frame

#### Etcetera.

If you call up the above examples, you'll see that the tidyverse alternative typically offers some enhancements or other useful options (and sometimes restrictions) over its base counterpart.

# Tidyverse vs. base R (cont.)

One point of convenience is that there is often a direct correspondence between a tidyverse command and its base R equivalent.

These generally follow a tidyverse::snake\_case vs base::period.case rule. E.g. Compare:

tidyverse	base
?readr::read_csv	<pre>?utils::read.csv</pre>
?dplyr::if_else	?base::ifelse
<pre>?tibble::tibble</pre>	?base::data.frame

#### Etcetera.

If you call up the above examples, you'll see that the tidyverse alternative typically offers some enhancements or other useful options (and sometimes restrictions) over its base counterpart.

**Remember:** There are (almost) always multiple ways to achieve a single goal in R.

# Tidyverse packages

Let's load the tidyverse meta-package and check the output.

# Tidyverse packages

Let's load the tidyverse meta-package and check the output.

We see that we have actually loaded a number of packages (which could also be loaded individually): **ggplot2**, **tibble**, **dplyr**, etc.

 We can also see information about the package versions and some namespace conflicts.

# Tidyverse packages (cont.)

The tidyverse actually comes with a lot more packages than those that are just loaded automatically.<sup>1</sup>

```
tidyverse packages()
                               "cravon"
                                           "dbplvr"
                                                       "dplyr"
   [1] "broom"
                   "cli"
   [6] "forcats" "ggplot2"
                               "haven"
                                           "hms"
                                                       "httr"
                   "lubridate" "magrittr" "modelr"
                                                      "pillar"
  [11] "jsonlite"
                                         "reprex"
                                                       "rlang"
## [16] "purrr"
                   "readr"
                               "readxl"
                                                       "tidvr"
                               "stringr"
                                          "tibble"
## [21] "rstudioapi" "rvest"
                   "tidvverse"
## [26] "xml2"
```

We'll use several of these additional packages during the remainder of this course.

- E.g. The **lubridate** package for working with dates and the **rvest** package for webscraping.
- However, bear in mind that these packages will have to be loaded separately.

<sup>&</sup>lt;sup>1</sup> It also includes a *lot* of dependencies upon installation. This is a matter of some controversy.

# Tidyverse packages (cont.)

I hope to cover most of the tidyverse packages over the length of this course.

Today, however, I'm only really going to focus on two packages:

- 1. dplyr
- 2. tidyr

These are the workhorse packages for cleaning and wrangling data. They are thus the ones that you will likely make the most use of (alongside **ggplot2**, which we already met back in Lecture 1).

• Data cleaning and wrangling occupies an inordinate amount of time, no matter where you are in your research career.

# An aside on pipes: %>%

We already learned about pipes in our lecture on the bash shell. The tidyverse loads its own pipe operator, denoted %>%.

I want to reiterate how cool pipes are, and how using them can dramatically improve the experience of reading and writing code. Compare:

```
## These next two lines of code do exactly the same thing.
mpg %>% filter(manufacturer="audi") %>% group_by(model) %>% summarise(hwy_mean = mear
summarise(group_by(filter(mpg, manufacturer="audi"), model), hwy_mean = mean(hwy))
```

# An aside on pipes: %>%

We already learned about pipes in our lecture on the bash shell. The tidyverse loads its own pipe operator, denoted %>%.

I want to reiterate how cool pipes are, and how using them can dramatically improve the experience of reading and writing code. Compare:

```
## These next two lines of code do exactly the same thing.
mpg %>% filter(manufacturer="audi") %>% group_by(model) %>% summarise(hwy_mean = mean
summarise(group_by(filter(mpg, manufacturer="audi"), model), hwy_mean = mean(hwy))
```

The first line reads from left to right, exactly how I thought of the operations in my head.

• Take this object (mpg), do this (filter), then do this (group\_by), etc.

The second line totally inverts this logical order (the final operation comes first!)

Who wants to read things inside out?

# An aside on pipes: %>% (cont.)

The piped version of the code is even more readable if we write it over several lines. Here it is again and, this time, I'll run it for good measure so you can see the output:

Remember: Using vertical space costs nothing and makes for much more readable/writeable code than cramming things horizontally.

# An aside on pipes: %>% (cont.)

The piped version of the code is even more readable if we write it over several lines. Here it is again and, this time, I'll run it for good measure so you can see the output:

```
mpg %>%
  filter(manufacturer="audi") %>%
  group by(model) %>%
  summarise(hwv mean = mean(hwv))
## # A tibble: 3 x 2
    model
             hwy mean
###
    <chr>
                <dbl>
          28.3
## 1 a4
## 2 a4 quattro
             25.8
## 3 a6 quattro
              24
```

Remember: Using vertical space costs nothing and makes for much more readable/writeable code than cramming things horizontally.

PS — The pipe is originally from the **magrittr** package (geddit?), which can do some other cool things if you're inclined to explore.

# A further aside on the base R pipe: |>

The magrittr pipe has proven so successful and popular, that the R core team recently announced a "native" pipe would be coming to base R, denoted  $\triangleright$ .<sup>1</sup> For example:

```
mtcars \triangleright subset(cyl=4) \triangleright head() mtcars \triangleright subset(cyl=4) \triangleright d \Rightarrow lm(mpg ~ disp, data = d)
```

<sup>&</sup>lt;sup>1</sup> That's actually a | followed by a >. The default font on these slides just makes it look extra fancy.

# A further aside on the base R pipe: |>

The magrittr pipe has proven so successful and popular, that the R core team recently announced a "native" pipe would be coming to base R, denoted  $\triangleright$ .<sup>1</sup> For example:

```
mtcars \triangleright subset(cyl=4) \triangleright head()
mtcars \triangleright subset(cyl=4) \triangleright d \Rightarrow lm(mpg ~ disp, data = d)
```

At the time of writing this native pipe is only available in the development version of R. (I'll show an in-class demo.)

This native pipe complements some other new cool features, like support for "lambda" functions in R.

• So, worth watching this space.

<sup>&</sup>lt;sup>1</sup> That's actually a | followed by a >. The default font on these slides just makes it look extra fancy.

# dplyr

# Aside: dplyr 1.0.0 release

Some of the **dplyr** features that we'll cover today were introduced in version 1.0.0 of the package.

- Version 1.0.0 is a big deal since it marks a stable code base for the package going forward. However, at the time of writing these slides, it had only come out very recently.
- Please make sure that you are running at least **dplyr** 1.0.0 before continuing.

```
packageVersion('dplyr')
## [1] '1.0.5'
# install.packages('dplyr') ## install updated version if < 1.0.0</pre>
```

# Aside: dplyr 1.0.0 release

Some of the **dplyr** features that we'll cover today were introduced in version 1.0.0 of the package.

- Version 1.0.0 is a big deal since it marks a stable code base for the package going forward. However, at the time of writing these slides, it had only come out very recently.
- Please make sure that you are running at least **dplyr** 1.0.0 before continuing.

```
packageVersion('dplyr')
## [1] '1.0.5'
# install.packages('dplyr') ## install updated version if < 1.0.0</pre>
```

*Note:* **dplyr** 1.0.0 also notifies you about grouping variables every time you do operations on or with them. YMMV, but, personally, I find these messages annoying and so prefer to switch them off.

```
options(dplyr.summarise.inform = FALSE) ## Add to .Rprofile to make permanent
```

# Key dplyr verbs

There are five key dplyr verbs that you need to learn.

- 1. filter: Filter (i.e. subset) rows based on their values.
- 2. arrange: Arrange (i.e. reorder) rows based on their values.
- 3. select : Select (i.e. subset) columns by their names:
- 4. mutate: Create new columns.
- 5. summarise: Collapse multiple rows into a single summary value. 1

<sup>&</sup>lt;sup>1</sup> summarize with a "z" works too. R doesn't discriminate against uncivilised nations of the world.

# Key dplyr verbs

There are five key dplyr verbs that you need to learn.

- 1. filter: Filter (i.e. subset) rows based on their values.
- 2. arrange: Arrange (i.e. reorder) rows based on their values.
- 3. select: Select (i.e. subset) columns by their names:
- 4. mutate: Create new columns.
- 5. summarise: Collapse multiple rows into a single summary value. 1

Let's practice these commands together using the starwars data frame that comes prepackaged with dplyr.

<sup>&</sup>lt;sup>1</sup> summarize with a "z" works too. R doesn't discriminate against uncivilised nations of the world.

# 1) dplyr::filter

We can chain multiple filter commands with the pipe (%>%), or just separate them within a single filter command using commas.

```
starwars %>%
  filter(
    species = "Human",
    height ≥ 190
## # A tibble: 4 x 14
###
    name
          height mass hair color skin color eye color birth year sex
                                                                      gender
    <chr> <int> <dbl> <chr>
                                 <chr>
                                                          <dbl> <chr> <chr>
                                            <chr>
###

### 3) dplyr::select

Use commas to select multiple columns out of a data frame. (You can also use "first:last" for consecutive columns). Deselect a column with "-".

```
starwars %>%
  select(name:skin color, species, -height)
## # A tibble: 87 x 5
                         mass hair color
                                          skin color
                                                       species
##
      name
   <chr>
                        <dhl> <chr>
                                            <chr>

If you just want to rename columns without subsetting them, you can use rename. Try this now by replacing select(...) in the above code chunk with rename(...).

The select(contains(PATTERN)) option provides a nice shortcut in relevant cases.

```
starwars %>%
  select(name, contains("color"))
## # A tibble: 87 x 4
                      hair color
                                   skin color eye color
##
     name
   <chr>
                      <chr>
                                   <chr>
                                             <chr>>
###
  1 Luke Skywalker
                      blond
                                  fair blue
###
                                   gold yellow
###

```

*Note:* The new relocate function available in dplyr 1.0.0 has brought a lot more functionality to ordering of columns. See here.

### 4) dplyr::mutate

You can create new columns from scratch, or (more commonly) as transformations of existing columns.

```
starwars %>%
  select(name, birth year) %>%
  mutate(dog years = birth year * 7) %>%
  mutate(comment = paste0(name, " is ", dog years, " in dog years."))
## # A tibble: 87 x 4
###
                         birth year dog years comment
     name
                              < [db] >
                                        <dbl> <chr>
###
   <chr>

## # ... with 77 more rows
```

Boolean, logical and conditional operators all work well with mutate too.

150

## 5 LEIA ORGANA

Lastly, combining mutate with the new across feature in dplyr 1.0.0+ allows you to easily work on a subset of variables. For example:

```
starwars %>%
  select(name:eye color) %>%
  mutate(across(where(is.character), toupper)) %>%
  head(5)
## # A tibble: 5 x 6
###
                  height mass hair color skin color
                                                    eye color
    name
          <int> <dbl> <chr>
                                         <chr>
                                                    <chr>>
###
    <chr>
## 1 LUKE SKYWALKER 172 77 BLOND
                                         FAIR
                                                    BLUE
## 2 C-3PO
                     167 75 <NA>
                                         GOLD
                                                    YELLOW
## 3 R2-D2
                                         WHITE, BLUE RED
                    96 32 <NA>
## 4 DARTH VADER
                     202

```

LIGHT

BROWN

49 BROWN

Lastly, combining mutate with the new across feature in dplyr 1.0.0+ allows you to easily work on a subset of variables. For example:

```
starwars %>%
  select(name:eve color) %>%
  mutate(across(where(is.character), toupper)) %>%
  head(5)
## # A tibble: 5 x 6
###
                  height mass hair color skin color
                                                    eye color
    name
          <int> <dbl> <chr>
    <chr>
                                         <chr>
                                                    <chr>
## 1 LUKE SKYWALKER 172 77 BLOND
                                         FAIR
                                                    BLUE
## 2 C-3PO
                     167 75 <NA>
                                         GOLD
                                                    YELLOW
## 3 R2-D2
                                         WHITE, BLUE RED
                    96 32 <NA>
## 4 DARTH VADER
                     202
                          136 NONE
                                         WHITE
                                                    YELLOW
## 5 LEIA ORGANA
                     150
                           49 BROWN
                                         LIGHT
                                                    BROWN
```

Note: This workflow (i.e. combining mutate and across) supersedes the old "scoped" variants of mutate that you might have used previously. More details here and here.

#### 5) dplyr::summarise

Particularly useful in combination with the group\_by command.

```
starwars %>%
  group_by(species, gender) %>%
  summarise(mean height = mean(height, na.rm = TRUE))
## # A tibble: 42 x 3
## # Groups: species [38]
##
     species gender
                      mean height
   <chr> <chr>
                              <dbl>
##
   1 Aleena masculine
###
                                 79
   2 Besalisk masculine
                                198
###
   3 Cerean
               masculine
###
                                198
##
   4 Chagrian
               masculine
                                196
   5 Clawdite feminine
###
                                168
   6 Droid feminine
                                96
###
   7 Droid
               masculine
###
                                140
   8 Dug masculine
                                112
##
   9 Ewok masculine
                                88
###
## 10 Geonosian masculine
                                183
## # ... with 32 more rows
```

### 5) dplyr::summarise cont.

Note that including "na.rm = TRUE" (or, its alias "na.rm = T") is usually a good idea with summarise functions. Otherwise, any missing value will propogate to the summarised value too.

```
## Probably not what we want
starwars %>%
   summarise(mean height = mean(height))
## # A tibble: 1 x 1
    mean height
###
           <dbl>
###
## 1
              NA
## Much better
starwars %>%
   summarise(mean height = mean(height, na.rm = TRUE))
## # A tibble: 1 x 1
     mean height
###
           <dbl>
###
         174.
## 1
```

### 5) dplyr::summarise cont.

## 5 Clawdite

168

55

NaN

The same across -based workflow that we saw with mutate a few slides back also works with summarise. For example:

```
starwars %>%
  group by(species) %>%
  summarise(across(where(is.numeric), mean, na.rm=T)) %>%
  head(5)
## # A tibble: 5 x 4
###

## 1 Aleena 79
                       15
                                NaN
## 2 Besalisk
                198
                      102
                                NaN
## 3 Cerean
                    82
                                92
               198
## 4 Chagrian
             196
                      NaN
                                NaN
```

#### 5) dplyr::summarise cont.

The same across -based workflow that we saw with mutate a few slides back also works with summarise. For example:

```
starwars %>%
  group by(species) %>%
  summarise(across(where(is.numeric), mean, na.rm=T)) %>%
  head(5)
## # A tibble: 5 x 4
###
    species height mass birth year
    <chr> <dbl> <dbl>
                              <dbl>
###
## 1 Aleena 79
                      15
                                NaN
## 2 Besalisk
              198 102
                                NaN
                    82
                               92
## 3 Cerean
           198
## 4 Chagrian 196
                     NaN
                                NaN
## 5 Clawdite
                168
                      55
                                NaN
```

Note: Again, this functionality supersedes the old "scoped" variants of summarise that you used prior to dplyr 1.0.0. Details here and here.

```
group_by and ungroup: For (un)grouping.
```

• Particularly useful with the summarise and mutate commands, as we've already seen.

```
group_by and ungroup: For (un)grouping.
```

• Particularly useful with the summarise and mutate commands, as we've already seen.

slice: Subset rows by position rather than filtering by values.

• E.g. starwars %>% slice(c(1, 5))

```
group_by and ungroup: For (un)grouping.
```

• Particularly useful with the summarise and mutate commands, as we've already seen.

slice: Subset rows by position rather than filtering by values.

• E.g. starwars %>% slice(c(1, 5))

pull: Extract a column from as a data frame as a vector or scalar.

• E.g. starwars %>% filter(gender="female") %>% pull(height)

```
group_by and ungroup: For (un)grouping.
```

• Particularly useful with the summarise and mutate commands, as we've already seen.

slice: Subset rows by position rather than filtering by values.

• E.g. starwars %>% slice(c(1, 5))

pull: Extract a column from as a data frame as a vector or scalar.

• E.g. starwars %>% filter(gender="female") %>% pull(height)

count and distinct: Number and isolate unique observations.

- E.g. starwars %>% count(species), Or starwars %>% distinct(species)
- You could also use a combination of mutate, group\_by, and n(), e.g. starwars %>% group\_by(species) %>% mutate(num = n()).

### Other dplyr goodies (cont.)

There are also a whole class of window functions for getting leads and lags, ranking, creating cumulative aggregates, etc.

• See vignette("window-functions").

### Other dplyr goodies (cont.)

There are also a whole class of window functions for getting leads and lags, ranking, creating cumulative aggregates, etc.

• See vignette("window-functions").

The final set of dplyr "goodies" are the family of join operations. However, these are important enough that I want to go over some concepts in a bit more depth...

• We will encounter and practice these many more times as the course progresses.

#### Joins

One of the mainstays of the dplyr package is merging data with the family join operations.

```
• inner_join(df1, df2)
```

- left\_join(df1, df2)
- right\_join(df1, df2)
- full\_join(df1, df2)
- semi\_join(df1, df2)
- anti\_join(df1, df2)

(You find find it helpful to to see visual depictions of the different join operations here.)

#### Joins

One of the mainstays of the dplyr package is merging data with the family join operations.

```
inner_join(df1, df2)
left_join(df1, df2)
right_join(df1, df2)
full_join(df1, df2)
semi_join(df1, df2)
```

anti join(df1, df2)

(You find find it helpful to to see visual depictions of the different join operations here.)

For the simple examples that I'm going to show here, we'll need some data sets that come bundled with the **nycflights13** package.

Load it now and then inspect these data frames in your own console.

```
library(nycflights13)
flights
planes
```

Let's perform a left join on the flights and planes datasets.

• Note: I'm going subset columns after the join, but only to keep text on the slide.

Let's perform a left join on the flights and planes datasets.

• Note: I'm going subset columns after the join, but only to keep text on the slide.

```
left join(flights, planes) %>%
   select(year, month, day, dep_time, arr_time, carrier, flight, tailnum, type, model)
## Joining, by = c("year", "tailnum")
## # A tibble: 336,776 x 10
                    day dep time arr time carrier flight tailnum type
##
       vear month
                                                                         model
                                                    <int> <chr> <chr> <chr>

   # ... with 336,766 more rows
```

(continued from previous slide)

Note that dplyr made a reasonable guess about which columns to join on (i.e. columns that share the same name). It also told us its choices:

```
## Joining, by = c("year", "tailnum")
```

However, there's an obvious problem here: the variable "year" does not have a consistent meaning across our joining datasets!

• In one it refers to the *year of flight*, in the other it refers to *year of construction*.

(continued from previous slide)

Note that dplyr made a reasonable guess about which columns to join on (i.e. columns that share the same name). It also told us its choices:

```
## Joining, by = c("year", "tailnum")
```

However, there's an obvious problem here: the variable "year" does not have a consistent meaning across our joining datasets!

• In one it refers to the year of flight, in the other it refers to year of construction.

Luckily, there's an easy way to avoid this problem.

- See if you can figure it out before turning to the next slide.
- Try ?dplyr::join.

(continued from previous slide)

You just need to be more explicit in your join call by using the by = argument.

• You can also rename any ambiguous columns to avoid confusion.

```
left join(
  flights,
  planes %>% rename(year built = year), ## Not necessary w/ below line, but helpful
  by = "tailnum" ## Be specific about the joining column
  ) %>%
  select(year, month, day, dep time, arr time, carrier, flight, tailnum, year built, t
  head(3) ## Just to save vertical space on the slide
## # A tibble: 3 x 11
     year month day dep time arr time carrier flight tailnum year built type

## 3
```

Make sure you know what "year.x" and "year.y" are. Again, it pays to be specific.

# tidyr

### Key tidyr verbs

- 1. pivot\_longer: Pivot wide data into long format (i.e. "melt").1
- 2. pivot\_wider: Pivot long data into wide format (i.e. "cast").<sup>2</sup>
- 3. separate: Separate (i.e. split) one column into multiple columns.
- 4. unite: Unite (i.e. combine) multiple columns into one.

<sup>&</sup>lt;sup>1</sup> Updated version of tidyr::gather.

<sup>&</sup>lt;sup>2</sup> Updated version of tidyr::spread.

### Key tidyr verbs

- 1. pivot\_longer: Pivot wide data into long format (i.e. "melt").1
- 2. pivot\_wider: Pivot long data into wide format (i.e. "cast").<sup>2</sup>
- 3. separate: Separate (i.e. split) one column into multiple columns.
- 4. unite: Unite (i.e. combine) multiple columns into one.

Let's practice these verbs together in class.

• Side question: Which of pivot\_longer vs pivot\_wider produces "tidy" data?

<sup>&</sup>lt;sup>1</sup> Updated version of tidyr::gather.

<sup>&</sup>lt;sup>2</sup> Updated version of tidyr::spread.

### 1) tidyr::pivot\_longer

-6.05

## 6 2009-01-02 Z

```
stocks = data.frame( ## Could use "tibble" instead of "data.frame" if you prefer
  time = as.Date('2009-01-01') + 0:1,
  X = rnorm(2, 0, 1),
  Y = rnorm(2, 0, 2),
  Z = rnorm(2. 0. 4)
stocks
          time X
###
## 1 2009-01-01 0.7630456 -0.7002949 -3.417682
## 2 2009-01-02 -0.4579186 -0.7498116 -6.052036
stocks %>% pivot longer(-time, names to="stock", values to="price")
## # A tibble: 6 x 3
##
  time stock price
   <date> <chr> <dbl>
##
## 1 2009-01-01 X 0.763
## 2 2009-01-01 Y -0.700
## 3 2009-01-01 Z -3.42
## 4 2009-01-02 X -0.458
## 5 2009-01-02 Y -0.750
                                                                              43 / 55
```

# 1) tidyr::pivot\_longer cont.

Let's quickly save the "tidy" (i.e. long) stocks data frame for use on the next slide.

```
## Write out the argument names this time: i.e. "names_to=" and "values_to="
tidy_stocks =
  stocks %>%
  pivot_longer(-time, names_to="stock", values_to="price")
```

### 2) tidyr::pivot\_wider

## 3 Z -3.42 -6.05

```
tidy stocks %>% pivot wider(names from=stock, values from=price)
## # A tibble: 2 x 4
  time X Y Z
###
    <date> <dbl> <dbl> <dbl>
###
## 1 2009-01-01 0.763 -0.700 -3.42
## 2 2009-01-02 -0.458 -0.750 -6.05
tidy stocks %>% pivot wider(names from=time, values from=price)
## # A tibble: 3 x 3
## stock 2009-01-01 2009-01-02
## <chr> <dbl> <dbl>
## 1 X 0.763 -0.458
## 2 Y -0.700 -0.750
```

## 2) tidyr::pivot\_wider

```
tidy stocks %>% pivot wider(names from=stock, values from=price)
## # A tibble: 2 x 4
   time X Y Z
##
    <date> <dbl> <dbl> <dbl>
###
## 1 2009-01-01 0.763 -0.700 -3.42
## 2 2009-01-02 -0.458 -0.750 -6.05
tidy stocks %>% pivot wider(names from=time, values from=price)
## # A tibble: 3 x 3
## stock 2009-01-01 2009-01-02
## <chr> <dbl> <dbl>
## 1 X 0.763 -0.458
## 2 Y -0.700 -0.750
## 3 Z -3.42 -6.05
```

Note that the second example — which has combined different pivoting arguments — has effectively transposed the data.

#### Aside: Remembering the pivot\_\* syntax

There's a long-running joke about no-one being able to remember Stata's "reshape" command. (Exhibit A.)

It's easy to see this happening with the pivot\_\* functions too. However, I find that I never forget the commands as long as I remember the argument order is "names" then "values".

## 3) tidyr::separate

```
economists = data.frame(name = c("Adam.Smith", "Paul.Samuelson", "Milton.Friedman"))
economists
##
               name
         Adam, Smith
## 2 Paul.Samuelson
## 3 Milton.Friedman
economists %>% separate(name, c("first_name", "last_name"))
    first_name last_name
###
          Adam
                   Smith
## 1
     Paul Samuelson
## 2
## 3 Milton Friedman
```

## 3) tidyr::separate

```
economists = data.frame(name = c("Adam.Smith", "Paul.Samuelson", "Milton.Friedman"))
economists
##
                name
         Adam. Smith
## 2 Paul.Samuelson
## 3 Milton.Friedman
economists %>% separate(name, c("first name", "last name"))
###
    first name last name
          Adam
                   Smith
## 1
     Paul Samuelson
     Milton Friedman
## 3
```

This command is pretty smart. But to avoid ambiguity, you can also specify the separation character with separate(..., sep=".").

## 3) tidyr::separate cont.

## 2 Jill Philosopher

## 4 Jill Troublemaker

## 3 Jill Philanthropist

A related function is separate\_rows, for splitting up cells that contain multiple fields or observations (a frustratingly common occurrence with survey data).

```
jobs = data.frame(
  name = c("Jack", "Jill"),
  occupation = c("Homemaker", "Philosopher, Philanthropist, Troublemaker")
iobs
###
                                          occupation
     name
                                           Homemaker
## 1 Jack
## 2 Jill Philosopher, Philanthropist, Troublemaker
## Now split out Jill's various occupations into different rows
jobs %>% separate rows(occupation)
## # A tibble: 4 x 2
    name occupation
###
    <chr> <chr>
## 1 Jack Homemaker
```

## 4) tidyr::unite

```
gdp = data.frame(
  yr = rep(2016, times = 4),
  mnth = rep(1, times = 4),
  dv = 1:4.
  gdp = rnorm(4, mean = 100, sd = 2)
gdp
## yr mnth dy gdp
## 2 2016 1 2 100.4228
## 3 2016 1 3 102.3959
## 4 2016 1 4 101.8645
## Combine "yr", "mnth", and "dy" into one "date" column
gdp %>% unite(date, c("yr", "mnth", "dy"), sep = "-")
  date gdp
##
## 1 2016-1-1 101.6175
## 2 2016-1-2 100.4228
## 3 2016-1-3 102.3959
## 4 2016-1-4 101.8645
```

## 4) tidyr::unite cont.

Note that unite will automatically create a character variable. You can see this better if we convert it to a tibble.

## 4) tidyr::unite cont.

Note that unite will automatically create a character variable. You can see this better if we convert it to a tibble.

If you want to convert it to something else (e.g. date or numeric) then you will need to modify it using mutate. See the next slide for an example, using the lubridate package's super helpful date conversion functions.

# 4) tidyr::unite cont.

(continued from previous slide)

# Other tidyr goodies

Use crossing to get the full combination of a group of variables.<sup>1</sup>

```
crossing(side=c("left", "right"), height=c("top", "bottom"))

## # A tibble: 4 x 2

## side height

## <chr> <chr>
## 1 left bottom

## 2 left top

## 3 right bottom

## 4 right top
```

<sup>&</sup>lt;sup>1</sup> Base R alternative: expand.grid.

## Other tidyr goodies

Use crossing to get the full combination of a group of variables.<sup>1</sup>

```
crossing(side=c("left", "right"), height=c("top", "bottom"))

## # A tibble: 4 x 2

## side height

## <chr> <chr>
## 1 left bottom

## 2 left top

## 3 right bottom

## 4 right top
```

See ?expand and ?complete for more specialised functions that allow you to fill in (implicit) missing data or variable combinations in existing data frames.

You'll encounter this during your next assignment.

<sup>&</sup>lt;sup>1</sup> Base R alternative: expand.grid.

# Summary

# Key verbs

#### dplyr

- 1. filter
- 2. arrange
- 3. select
- 4. mutate
- 5. summarise

#### tidyr

- 1. pivot\_longer
- 2. pivot\_wider
- 3. separate
- 4. unite

#### Key verbs

#### dplyr

- 1. filter
- 2. arrange
- 3. select
- 4. mutate
- 5. summarise

#### tidyr

- 1. pivot\_longer
- 2. pivot\_wider
- 3. separate
- 4. unite

Other useful items include: pipes (%>%), grouping (group\_by), joining functions (left\_join, inner\_join, etc.).
