Data Science for Economists

Lecture 5: Data cleaning & wrangling: (1) Tidyverse

Grant McDermott, adapted by Kyle Coombs Bates College | EC/DCS 368

Table of contents

- 1. Prologue
- 2. Tidyverse basics
- 3. Data wrangling with dplyr
 - filter
 - arrange
 - select
 - mutate
 - summarise
 - joins
- 4. Data tidying with tidyr
 - pivot_longer / pivot_wider
 - separate
 - unite
- 5. Summary

Prologue

Housekeeping

- Full version of these slides available on Grant McDermott's website
- Problem Set 2 has been posted and is due 10/9 by Midnight
- Sync your fork, pull the latest changes to your computer

What is "tidy" data?

Resources:

- Vignette (from the **tidyr** package)
- Original paper (Hadley Wickham, 2014 JSS)

What is "tidy" data?

Resources:

- Vignette (from the **tidyr** package)
- Original paper (Hadley Wickham, 2014 JSS)

Key points:

- 1. Each variable forms a column.
- 2. Each observation forms a row.
- 3. Each type of observational unit forms a table.

What is "tidy" data?

Resources:

- Vignette (from the **tidyr** package)
- Original paper (Hadley Wickham, 2014 JSS)

Key points:

- 1. Each variable forms a column.
- 2. Each observation forms a row.
- 3. Each type of observational unit forms a table.

Basically, tidy data is more likely to be long (i.e. narrow) format than wide format.

Checklist

R packages you'll need for this lecture

- **☑** tidyverse
- **☑** nycflights13

Checklist

R packages you'll need for this lecture

- **☑** tidyverse
- **☑** nycflights13

The following code chunk will install (if necessary) and load everything for you.

```
if (!require(pacman)) install.packages('pacman', repos = 'https://cran.rstudio.com')
pacman::p_load(tidyverse, data.table, dtplyr, tidyfast, microbenchmark, ggplot2, nycfl
```

Tip: If you're on Linux, then I *strongly* recommend installing the pre-compiled binary versions of these packages from RSPM instead of CRAN. The exact repo mirror varies by distro (see the link). But on Ubuntu 20.04, for example, you'd use:

```
install.packages(c('tidyverse', 'nycflights13','data.table','dtplyr','tidyfast','micro
library(tidyverse)
library(data.table)
#etc.
```

6 / 51

Tidyverse basics

Tidyverse vs. base R

Much digital ink has been spilled over the "tidyverse vs. base R" debate.

Tidyverse vs. base R

Much digital ink has been spilled over the "tidyverse vs. base R" debate.

I won't delve into this debate here, because I think the answer is clear: We should teach the tidyverse first (or, at least, early).

- The documentation and community support are outstanding.
- Having a consistent philosophy and syntax makes it easier to learn.
- Provides a convenient "front-end" to big data tools that we'll use later in the course.
- For data cleaning, wrangling, and plotting, the tidyverse really is a no-brainer.¹

¹ I'm also a huge fan of **data.table**. This package will be the subject of our next lecture.

Tidyverse vs. base R

Much digital ink has been spilled over the "tidyverse vs. base R" debate.

I won't delve into this debate here, because I think the answer is clear: We should teach the tidyverse first (or, at least, early).

- The documentation and community support are outstanding.
- Having a consistent philosophy and syntax makes it easier to learn.
- Provides a convenient "front-end" to big data tools that we'll use later in the course.
- For data cleaning, wrangling, and plotting, the tidyverse really is a no-brainer. 1

But... this certainly shouldn't put you off learning base R alternatives.

- Base R is extremely flexible and powerful (and stable).
- There are some things that you'll have to venture outside of the tidyverse for.
- A combination of tidyverse and base R is often the best solution to a problem.
- Excellent base R data manipulation tutorials: here and here.

¹ I'm also a huge fan of **data.table**. This package will be the subject of our next lecture.

Tidyverse vs. base R (cont.)

One point of convenience is that there is often a direct correspondence between a tidyverse command and its base R equivalent.

These generally follow a tidyverse::snake_case VS base::period.case rule. E.g. Compare:

tidyverse	base
?readr::read_csv	<pre>?utils::read.csv</pre>
?dplyr::if_else	<pre>?base::ifelse</pre>
<pre>?tibble::tibble</pre>	?base::data.frame

Etcetera.

If you call up the above examples, you'll see that the tidyverse alternative typically offers some enhancements or other useful options (and sometimes restrictions) over its base counterpart.

Tidyverse vs. base R (cont.)

One point of convenience is that there is often a direct correspondence between a tidyverse command and its base R equivalent.

These generally follow a tidyverse::snake_case vs base::period.case rule. E.g. Compare:

tidyverse	base
?readr::read_csv	<pre>?utils::read.csv</pre>
?dplyr::if_else	<pre>?base::ifelse</pre>
<pre>?tibble::tibble</pre>	?base::data.frame

Etcetera.

If you call up the above examples, you'll see that the tidyverse alternative typically offers some enhancements or other useful options (and sometimes restrictions) over its base counterpart.

Remember: There are (almost) always multiple ways to achieve a single goal in R.

Tidyverse packages

Let's load the tidyverse meta-package and check the output.

library(tidyverse)

Tidyverse packages

Let's load the tidyverse meta-package and check the output.

```
library(tidyverse)
```

We see that we have actually loaded a number of packages (which could also be loaded individually): **ggplot2**, **tibble**, **dplyr**, etc.

• We can also see information about the package versions and some namespace conflicts.

Tidyverse packages (cont.)

The tidyverse actually comes with a lot more packages than those that are just loaded automatically.¹

```
tidvverse packages()
                         "conflicted"
                                           "cli"
                                                            "dbplvr"
    [1] "broom"
##
                                                            "ggplot2"
    [5] "dplvr"
                         "dtplvr"
                                           "forcats"
    [9] "googledrive"
                          "googlesheets4" "haven"
                                                            "hms"
   [13] "httr"
                         "isonlite"
                                           "lubridate"
                                                            "magrittr"
                         "pillar"
                                           "purrr"
                                                            "ragg"
   [17] "modelr"
                                           "reprex"
                                                            "rlang"
                         "readxl"
   [21] "readr"
   [25] "rstudioapi"
                          "rvest"
                                           "stringr"
                                                            "tibble"
   [29] "tidvr"
                          "xml2"
                                           "tidvverse"
```

We'll use several of these additional packages during the remainder of this course.

- E.g. The **lubridate** package for working with dates and the **rvest** package for webscraping.
- However, bear in mind that these packages will have to be loaded separately. It also includes a lot of dependencies upon installation. This is a matter of some controversy.

Tidyverse packages (cont.)

I hope to cover most of the tidyverse packages over the length of this course.

Today, however, I'm only really going to focus on two packages:

- 1. dplyr
- 2. tidyr

These are the workhorse packages for cleaning and wrangling data. They are thus the ones that you will likely make the most use of (alongside **ggplot2**, which we already met back in Lecture 1).

• Data cleaning and wrangling occupies an inordinate amount of time, no matter where you are in your research career.

dplyr

dplyr

Note: **dplyr** 1.0.0 also notifies you about grouping variables every time you do operations on or with them. YMMV, but, personally, I find these messages annoying and so prefer to switch them off.

options(dplyr.summarise.inform = FALSE) ## Add to .Rprofile to make permanent

Key dplyr verbs

There are five key dplyr verbs that you need to learn.

- 1. filter: Filter (i.e. subset) rows based on their values.
- 2. arrange: Arrange (i.e. reorder) rows based on their values.
- 3. select: Select (i.e. subset) columns by their names:
- 4. mutate: Create new columns.
- 5. summarise: Collapse multiple rows into a single summary value. 1

¹ summarize with a "z" works too, but Hadley Wickham is from New Sealand.

Key dplyr verbs

There are five key dplyr verbs that you need to learn.

- 1. filter: Filter (i.e. subset) rows based on their values.
- 2. arrange: Arrange (i.e. reorder) rows based on their values.
- 3. select: Select (i.e. subset) columns by their names:
- 4. mutate: Create new columns.
- 5. summarise: Collapse multiple rows into a single summary value. 1

Let's practice these commands together using the starwars data frame that comes prepackaged with dplyr.

¹ summarize with a "z" works too, but Hadley Wickham is from New Sealand.

1) dplyr::filter

We can chain multiple filter commands with the pipe %>% ¹, or just separate them within a single filter command using commas.

```
starwars %>%
filter(
   species = "Human",
   height \ge 190
)
```

```
# A tibble: 4 × 14
               height
                       mass hair color skin color eye color birth year sex
##
     name
                                                                                  gender
              <int> <dbl> <chr>
     <chr>>
                                         <chr>>
                                                     <chr>>
                                                                     <dbl> <chr> <chr>

```

1) dplyr::filter cont.

A very common filter use case is identifying (or removing) missing data cases.

```
starwars %>%
  filter(is.na(height))
## # A tibble: 6 × 14
              height mass hair color skin color eye color birth year sex
                                                                           gender
##
    name
    <chr>
          <int> <dbl> <chr>
                                      <chr>
                                                <chr>
                                                               <dbl> <chr> <chr>

## 6 Captain ...
                  NA NA unknown
                                      unknown
                                                unknown
                                                                  NA <NA> <NA>
## # i 5 more variables: homeworld <chr>, species <chr>, films <list>,
     vehicles <list>, starships <list>
## #
```

To remove missing observations, simply use negation: filter(!is.na(height)). Try this yourself.

2) dplyr::arrange

```
starwars %>%
   arrange(birth vear)
## # A tibble: 87 × 14
                height mass hair color skin color eye color birth year sex
##

Note: Arranging on a character-based column (i.e. strings) will sort alphabetically. Try this yourself by arranging according to the "name" column.

2) dplyr::arrange cont.

We can also arrange items in descending order using arrange(desc()).

```
starwars %>%
   arrange(desc(birth year))
## # A tibble: 87 × 14
               height mass hair color skin color eye color birth year sex

3) dplyr::select

Use commas to select multiple columns out of a data frame. (You can also use "first:last" for consecutive columns). Deselect a column with "-".

```
starwars %>%
  select(name:skin color, species, -height)
## # A tibble: 87 × 5
                         mass hair color
                                           skin color
                                                        species
##

## # i 77 more rows
```

If you just want to rename columns without subsetting them, you can use rename. Try this now by replacing select(...) in the above code chunk with rename(...).

3) dplyr::select cont.

The select(contains(PATTERN)) option provides a nice shortcut in relevant cases.

```
starwars %>%
  select(name, contains("color"))
## # A tibble: 87 × 4
                      hair color
                                   skin color eye color
##
     name
   <chr>
                      <chr>
                                   <chr>
                                              <chr>>
###
  1 Luke Skywalker
                      blond
                                   fair blue
###
                                   gold yellow

## # i 77 more rows
```

4) dplyr::mutate

You can create new columns from scratch, or (more commonly) as transformations of existing columns.

```
starwars %>%
  select(name, birth year) %>%
  mutate(dog years = birth year * 7) %>%
  mutate(comment = paste0(name, " is ", dog years, " in dog years."))
## # A tibble: 87 × 4
###
                         birth year dog years comment
     name
                              < [db] >
                                        <dbl> <chr>
###
   <chr>
   1 Luke Skywalker
                               19
                                         133 Luke Skywalker is 133 in dog years.
###
   2 C-3P0
                              112
                                         784 C-3PO is 784 in dog years.
###
   3 R2-D2
                               33
                                         231 R2-D2 is 231 in dog years.
###

                                              R5-D4 is NA in dog years.
   9 Biggs Darklighter
                                         168
                                              Biggs Darklighter is 168 in dog year...
                               24
  10 Obi-Wan Kenobi
                                              Obi-Wan Kenobi is 399 in dog years.
                               57
                                         399
                                                                                    25 / 51
  # i 77 more rows
```

4) dplyr::mutate cont.

Boolean, logical and conditional operators all work well with mutate too.

4) dplyr::mutate cont.

Lastly, combining mutate with the across feature allows you to easily work on a subset of variables. For example:

```
starwars %>%
  select(name:eye color) %>%
  mutate(across(where(is.character), \(x) toupper(x))) %>%
  head(5)
## # A tibble: 5 × 6
###
    name
                  height mass hair color skin color
                                                    eye color
          <int> <dbl> <chr>
                                         <chr>
                                                    <chr>>
###
    <chr>
## 1 LUKE SKYWALKER 172 77 BLOND
                                         FAIR
                                                    BLUE
## 2 C-3PO
                     167 75 <NA>
                                         GOLD
                                                    YELLOW
## 3 R2-D2
                                         WHITE, BLUE RED
                     96 32 <NA>
## 4 DARTH VADER
                     202
                           136 NONE
                                         WHITE
                                                    YELLOW
## 5 LEIA ORGANA
                     150
                            49 BROWN
                                         LIGHT
                                                    BROWN
```

5) dplyr::summarise

Particularly useful in combination with the group_by command.

```
starwars %>%
  group_by(species, gender) %>%
  summarise(mean height = mean(height, na.rm = TRUE))
## summarise() has grouped output by 'species'. You can override using the
## .groups argument.
## # A tibble: 42 × 3
## # Groups: species [38]
     species gender
                      mean height
##
   <chr> <chr>
                               <dbl>
##
   1 Aleena masculine
                                 79
###
   2 Besalisk masculine
                                198
###
   3 Cerean
               masculine
###
                                198
   4 Chagrian masculine
##
                                196
   5 Clawdite feminine
                                 168
###
   6 Droid feminine
                                96
###
   7 Droid masculine
                                 140
###
   8 Dug masculine
##
                                 112
          masculine
   9 Ewok
                                88
###
## 10 Geonosian masculine
                                 183
## # i 32 more rows
```

5) dplyr::summarise cont.

Note that including "na.rm = TRUE" (or, its alias "na.rm = T") is usually a good idea with summarise functions. Otherwise, your output will be missing too.

```
## Probably not what we want
starwars %>%
  summarise(mean height = mean(height))
## # A tibble: 1 × 1
    mean height
###
###
           <dbl>
## 1
              NA
## Much better
starwars %>%
  summarise(mean height = mean(height, na.rm = TRUE))
## # A tibble: 1 × 1
    mean height
##
           <dbl>
##
## 1 174.
```

5) dplyr::summarise cont.

The same across -based workflow that we saw with mutate a few slides back also works with summarise. For example:

```
starwars %>%
  group by(species) %>%
  summarise(across(where(is.numeric), \(x) (mean(x, na.rm=T)))) %>%
  head(5)
## # A tibble: 5 × 4
###
    species height mass birth year
    <chr> <dbl> <dbl>
                              <dbl>
###
## 1 Aleena 79
                      15
                                NaN
## 2 Besalisk
                198
                     102
                                NaN
                    82
                                92
## 3 Cerean
             198
## 4 Chagrian
             196
                     NaN
                                NaN
## 5 Clawdite
                168
                      55
                                NaN
```

```
group_by and ungroup: For (un)grouping.
```

• Particularly useful with the summarise and mutate commands, as we've already seen.

```
group_by and ungroup: For (un)grouping.
```

• Particularly useful with the summarise and mutate commands, as we've already seen.

slice: Subset rows by position rather than filtering by values.

• E.g. starwars %>% slice(c(1, 5))

```
group_by and ungroup: For (un)grouping.
```

• Particularly useful with the summarise and mutate commands, as we've already seen.

slice: Subset rows by position rather than filtering by values.

• E.g. starwars %>% slice(c(1, 5))

pull: Extract a column from as a data frame as a vector or scalar.

• E.g. starwars %>% filter(gender="female") %>% pull(height)

```
group_by and ungroup: For (un)grouping.
```

• Particularly useful with the summarise and mutate commands, as we've already seen.

slice: Subset rows by position rather than filtering by values.

• E.g. starwars %>% slice(c(1, 5))

pull: Extract a column from as a data frame as a vector or scalar.

• E.g. starwars %>% filter(gender="female") %>% pull(height)

count and distinct: Number and isolate unique observations.

- E.g. starwars %>% count(species), Or starwars %>% distinct(species)
- You could also use a combination of mutate, group_by, and n(), e.g. starwars %>% group_by(species) %>% mutate(num = n()).

Other dplyr goodies (cont.)

There are also a whole class of window functions for getting leads and lags, ranking, creating cumulative aggregates, etc.

• See vignette("window-functions").

Other dplyr goodies (cont.)

There are also a whole class of window functions for getting leads and lags, ranking, creating cumulative aggregates, etc.

• See vignette("window-functions").

The final set of dplyr "goodies" are the family of join operations. However, these are important enough that I want to go over some concepts in a bit more depth...

• We will encounter and practice these many more times as the course progresses.

Joins

One of the mainstays of the dplyr package is merging data with the family join operations.

```
• inner_join(df1, df2)
```

- left_join(df1, df2)
- right_join(df1, df2)
- full_join(df1, df2)
- semi_join(df1, df2)
- anti_join(df1, df2)

Joins are how you get Relational Database Managment (RDBM) to work in R.

(See visual depictions of the different join operations here.)

Joins

One of the mainstays of the dplyr package is merging data with the family join operations.

```
• inner_join(df1, df2)
```

- left_join(df1, df2)
- right_join(df1, df2)
- full_join(df1, df2)
- semi_join(df1, df2)
- anti_join(df1, df2)

Joins are how you get Relational Database Managment (RDBM) to work in R.

(See visual depictions of the different join operations here.)

For the simple examples that I'm going to show here, we'll need some data sets that come bundled with the **nycflights13** package.

• Load it now and then inspect these data frames in your own console.

```
library(nycflights13)
flights
planes
```

Let's perform a left join on the flights and planes datasets.

• Note: I'm going subset columns after the join, but only to keep text on the slide.

Let's perform a left join on the flights and planes datasets.

• Note: I'm going subset columns after the join, but only to keep text on the slide.

```
left join(flights, planes) %>%
   select(year, month, day, dep_time, arr_time, carrier, flight, tailnum, type, model)
## Joining with by = join by(year, tailnum)
## # A tibble: 336,776 × 10
                    day dep time arr time carrier flight tailnum type
##
       vear month
                                                                         model
                                                    <int> <chr> <chr> <chr>

                                                                                      34 / 51
```

(continued from previous slide)

Note that dplyr made a reasonable guess about which columns to join on (i.e. columns that share the same name). It also told us its choices:

```
## Joining, by = c("year", "tailnum")
```

However, there's a problem here: the variable "year" does not have a consistent meaning across our joining datasets!

• In one it refers to the *year of flight*, in the other it refers to *year of construction*.

(continued from previous slide)

Note that dplyr made a reasonable guess about which columns to join on (i.e. columns that share the same name). It also told us its choices:

```
## Joining, by = c("year", "tailnum")
```

However, there's a problem here: the variable "year" does not have a consistent meaning across our joining datasets!

• In one it refers to the year of flight, in the other it refers to year of construction.

Luckily, there's an easy way to avoid this problem.

- See if you can figure it out before turning to the next slide.
- Try ?dplyr::join.

(continued from previous slide)

You just need to be more explicit in your join call by using the by = argument.

• You can also rename any ambiguous columns to avoid confusion.

```
left_join(
  flights,
  planes %>% rename(year_built = year), ## Not necessary w/ below line, but helpful
  by = "tailnum" ## Be specific about the joining column
  ) %>%
  select(year, month, day, dep_time, arr_time, carrier, flight, tailnum, year_built, 1
  head(3) ## Just to save vertical space on the slide

## # A tibble: 3 × 11

## year month day dep_time arr_time carrier flight tailnum year_built type

Make sure you know what "year.x" and "year.y" are. Again, it pays to be specific.

tidyr

Key tidyr verbs

- 1. pivot_longer: Pivot wide data into long format (i.e. "melt").1
- 2. pivot_wider: Pivot long data into wide format (i.e. "cast").²
- 3. separate: Separate (i.e. split) one column into multiple columns.
- 4. unite: Unite (i.e. combine) multiple columns into one.

¹ Updated version of tidyr::gather.

² Updated version of tidyr::spread.

Key tidyr verbs

- 1. pivot_longer: Pivot wide data into long format (i.e. "melt").1
- 2. pivot_wider: Pivot long data into wide format (i.e. "cast").²
- 3. separate: Separate (i.e. split) one column into multiple columns.
- 4. unite: Unite (i.e. combine) multiple columns into one.

Let's practice these verbs together in class.

• Side question: Which of pivot_longer vs pivot_wider produces "tidy" data?

¹ Updated version of tidyr::gather.

² Updated version of tidyr::spread.

1) tidyr::pivot_longer

6.01

6 2009-01-02 Z

```
stocks = data.frame( ## Could use "tibble" instead of "data.frame" if you prefer
  time = as.Date('2009-01-01') + 0:1,
  X = rnorm(2, 0, 1),
  Y = rnorm(2, 0, 2),
  Z = rnorm(2. 0. 4)
stocks
              X
###
        time
## 1 2009-01-01 0.02307661 -2.082060 -2.217609
## 2 2009-01-02 1.24565052 -3.450151 6.013777
stocks %>% pivot longer(-time, names to="stock", values to="price")
## # A tibble: 6 × 3
##
  time stock price
  <date> <chr> <dbl>
##
## 1 2009-01-01 X 0.0231
## 2 2009-01-01 Y -2.08
## 3 2009-01-01 Z -2.22
## 4 2009-01-02 X 1.25
## 5 2009-01-02 Y -3.45
```

40 / 51

1) tidyr::pivot_longer cont.

Let's quickly save the "tidy" (i.e. long) stocks data frame for use on the next slide.

```
## Write out the argument names this time: i.e. "names_to=" and "values_to="
tidy_stocks =
  stocks %>%
  pivot_longer(-time, names_to="stock", values_to="price")
```

2) tidyr::pivot_wider

2 Y -2.08 -3.45 ## 3 Z -2.22 6.01

```
tidy stocks %>% pivot wider(names from=stock, values from=price)
## # A tibble: 2 × 4
  time X Y Z
###
  <date> <dbl> <dbl> <dbl>
###
## 1 2009-01-01 0.0231 -2.08 -2.22
## 2 2009-01-02 1.25 -3.45 6.01
tidy stocks %>% pivot wider(names from=time, values from=price)
## # A tibble: 3 × 3
## stock 2009-01-01 2009-01-02
## <chr> <dbl> <dbl>
## 1 X 0.0231 1.25
```

2) tidyr::pivot_wider

```
tidy stocks %>% pivot wider(names from=stock, values from=price)
## # A tibble: 2 × 4
  time X Y Z
###
    <date> <dbl> <dbl> <dbl> <dbl>
###
## 1 2009-01-01 0.0231 -2.08 -2.22
## 2 2009-01-02 1.25 -3.45 6.01
tidy stocks %>% pivot wider(names from=time, values from=price)
## # A tibble: 3 × 3
## stock 2009-01-01 2009-01-02
## <chr> <dbl> <dbl>
## 1 X 0.0231 1.25
## 2 Y -2.08 -3.45
## 3 Z -2.22 6.01
```

Note that the second example — which has combined different pivoting arguments — has effectively transposed the data.

Aside: Remembering the pivot_* syntax

There's a long-running joke about no-one being able to remember Stata's "reshape" command. (Exhibit A.)

It's easy to see this happening with the pivot_* functions too. However, I find that I never forget the commands as long as I remember the argument order is "names" then "values".

3) tidyr::separate

```
economists = data.frame(name = c("Adam.Smith", "Paul.Samuelson", "Milton.Friedman"))
economists
##
               name
         Adam, Smith
## 2 Paul.Samuelson
## 3 Milton.Friedman
economists %>% separate(name, c("first_name", "last_name"))
    first_name last_name
###
          Adam
                   Smith
## 1
     Paul Samuelson
## 2
## 3 Milton Friedman
```

3) tidyr::separate

```
economists = data.frame(name = c("Adam.Smith", "Paul.Samuelson", "Milton.Friedman"))
economists
##
                name
         Adam. Smith
## 2 Paul.Samuelson
## 3 Milton.Friedman
economists %>% separate(name, c("first name", "last name"))
###
    first name last name
          Adam
                   Smith
## 1
     Paul Samuelson
     Milton Friedman
## 3
```

This command is pretty smart. But to avoid ambiguity, you can also specify the separation character with separate(..., sep=".").

3) tidyr::separate cont.

2 Jill Philosopher

4 Jill Troublemaker

3 Jill Philanthropist

A related function is separate_rows, for splitting up cells that contain multiple fields or observations (a frustratingly common occurrence with survey data).

```
jobs = data.frame(
  name = c("Jack", "Jill"),
  occupation = c("Homemaker", "Philosopher, Philanthropist, Troublemaker")
iobs
###
                                          occupation
     name
                                           Homemaker
## 1 Jack
## 2 Jill Philosopher, Philanthropist, Troublemaker
## Now split out Jill's various occupations into different rows
jobs %>% separate rows(occupation)
## # A tibble: 4 × 2
    name occupation
###
    <chr> <chr>
## 1 Jack Homemaker
```

4) tidyr::unite

```
gdp = data.frame(
  yr = rep(2016, times = 4),
  mnth = rep(1, times = 4),
  dv = 1:4.
  gdp = rnorm(4, mean = 100, sd = 2)
gdp
## yr mnth dy gdp
## 2 2016 1 2 98.44948
## 3 2016 1 3 95.33033
## 4 2016 1 4 101.95293
## Combine "yr", "mnth", and "dy" into one "date" column
gdp %>% unite(date, c("yr", "mnth", "dy"), sep = "-")
  date gdp
##
## 1 2016-1-1 98.78633
## 2 2016-1-2 98.44948
## 3 2016-1-3 95.33033
## 4 2016-1-4 101,95293
```

4) tidyr::unite cont.

Note that unite will automatically create a character variable. You can see this better if we convert it to a tibble.

4) tidyr::unite cont.

Note that unite will automatically create a character variable. You can see this better if we convert it to a tibble.

If you want to convert it to something else (e.g. date or numeric) then you will need to modify it using mutate. See the next slide for an example, using the lubridate package's super helpful date conversion functions.

4) tidyr::unite cont.

(continued from previous slide)

Summary

Key verbs

dplyr

- 1. filter
- 2. arrange
- 3. select
- 4. mutate
- 5. summarise

tidyr

- 1. pivot_longer
- 2. pivot_wider
- 3. separate
- 4. unite

Key verbs

dplyr

- 1. filter
- 2. arrange
- 3. select
- 4. mutate
- 5. summarise

tidyr

- 1. pivot_longer
- 2. pivot_wider
- 3. separate
- 4. unite

Other useful items include: pipes (%>%), grouping (group_by), joining functions (left_join, inner_join, etc.).
